

BASAL CELL CARCINOMA

WHAT ARE THE AIMS OF THIS LEAFLET?

This leaflet has been written to help you understand more about basal cell carcinomas. It tells you about what they are, what causes them, what can be done about them and where you can find out more about them.

WHAT IS A BASAL CELL CARCINOMA?

A basal cell carcinoma (BCC) is a type of skin cancer. There are two main categories of skin cancer: melanoma and non-melanoma skin cancer. BCC is the most common type of non-melanoma skin cancer worldwide. In the UK, cases have increased by 39% between 2000-2011. BCCs are sometimes referred to as “rodent ulcers”.

WHAT CAUSES BASAL CELL CARCINOMA?

The most common cause is exposure to ultraviolet (UV) light from the sun or from sunbeds. BCCs can occur anywhere on the body but are most common on areas that are exposed to the sun such as your face, head, neck and ears. It can rarely develop in a longstanding scar or be a part of rare genetic syndromes. BCCs are not infectious.

BCCs mainly affect fair skinned adults, but other skin types are also at risk. Those with the highest risk of developing a basal cell carcinoma are:

- People with pale skin who burn easily and rarely tan (especially those with light coloured or red hair, although some people with dark hair still have fair skin).
- Those who have had a lot of exposure to the sun, such as people

with outdoor hobbies or outdoor workers, and people who have lived in sunny climates.

- People who have used sun beds or have regularly sunbathed.
- People who have previously had a basal cell carcinoma.

ARE BASAL CELL CARCINOMAS HEREDITARY?

Apart from some rare genetic conditions, such as one called Gorlin syndrome (<https://gorlinsyndrome.org/about-gorlin-syndrome/>), BCCs are not thought to be hereditary. However, some factors which increase the risk of getting one (e.g. a fair skin, a tendency to burn rather than tan, and freckling) do run in families.

WHAT DOES A BASAL CELL CARCINOMA LOOK LIKE?

BCCs can vary greatly in their appearance, but people often first become aware of them as a scab that bleeds and does not heal completely or a new red or pearly lump on the skin. Some BCCs are superficial and look like a scaly red flat mark on the skin. Others form a lump and have a pearl-like rim surrounding a central crater and there may be small red blood vessels present across the surface. If left untreated, BCCs can eventually cause an ulcer; hence the name “rodent ulcer”. Most BCCs are painless, although sometimes they can be itchy or bleed if caught.

HOW WILL MY BASAL CELL CARCINOMA BE DIAGNOSED?

Sometimes the diagnosis is clear from the clinical appearance. A skin biopsy can be performed under local anaesthetic to

confirm the diagnosis. A skin biopsy involves an injection of local anaesthetic into the skin to make it numb, then removal of a small piece of skin, which may be followed by a stitch.

CAN BASAL CELL CARCINOMAS BE CURED?

Yes, BCCs can be cured in almost every case, although treatment can be more complicated if the BCC has been neglected for a long time, or if it occurs in an awkward place to remove skin, such as close to the eye or on the nose or ear.

BCCs rarely spread to other parts of the body. Therefore, although it is a type of skin cancer it is almost never a danger to life. However, if a BCC is not treated early, it may get larger and may be more likely to come back. Large BCCs that are surgically treated may also leave larger scars, which may cause concern if they are on areas important to appearance, such as the face.

HOW CAN A BASAL CELL CARCINOMA BE TREATED?

The most common treatment for BCC is surgery. Usually, this means cutting away the BCC, along with some of the healthy skin around it, using local anaesthetic injection to numb the skin. The skin can usually be closed with stitches, but sometimes a skin graft is needed.

Other types of treatment include:

- *Mohs micrographic surgery* – This surgical procedure is used to treat more complex BCCs such as infiltrative type of BCC or recurrent BCCs at difficult anatomical sites. The procedure involves excision of the affected skin and examination of the skin removed under the microscope straight away to see if all of the BCC has been removed. If any residual BCC is left at the edge of the excision further skin is excised from that area and examined under the microscope. This process is continued until all of the BCC is removed. The resulting wound may be closed with stitches, perhaps with a skin graft or sometimes just left to heal naturally. This is a time-consuming process and is only undertaken when simple surgery may not be suitable.
- *Radiotherapy* – shining X-rays onto the area containing the BCC usually delivered by the oncology team over a number of days.
- *Vismodegib* – this is a type of chemotherapy that has become available for the treatment of very complex BCCs, e.g. locally advanced BCCs or the very rare BCC that has spread to other parts of the body. This treatment has limited availability in the UK NHS.
- *Superficial BCCs*:
 - *Curettage and cautery* – the skin is numbed with local anaesthetic and the BCC is scraped away (curettage) and then the skin surface is sealed by heat (cautery).
 - *Cryotherapy* – freezing the BCC with liquid nitrogen.
 - *Creams* – these can be applied to the skin. The two commonly used are *imiquimod cream* and *5-fluorouracil cream* (5-FU).
 - *Photodynamic therapy* – a special cream is applied to the BCC which is taken up by the cells that are then destroyed by exposure to a specific wavelength of light. This treatment is only available in certain dermatology departments.

BCC is often treated with surgery. The choice of other treatments depends on the

site and size of the BCC, the condition of the surrounding skin and number of BCC to be treated (some people have multiple). The overall state of health of each person to be treated is also taken into account. In some cases, the reasonable option is no treatment at all – this happens when the lesion is growing very slowly and is at a non-critical site of the body, in people with a low chance of recovery.

SELF-CARE (WHAT CAN I DO?)

Treatment will be much easier if your BCC is detected early. BCCs can vary in their appearance, but it is advisable to see your doctor if you have any marks or scabs on your skin which are:

- growing
- bleeding and never completely healing
- changing appearance in any way

Check your skin for changes once a month. A friend or family member can help you particularly with checking areas that you cannot easily inspect, such as your back.

You can also take some simple precautions to help prevent a BCC appearing:

Top sun safety tips:

- *Protect your skin with clothing, and don't forget to wear a hat that protects your face, neck and ears, and a pair of UV protective sunglasses.*
- *Spend time in the shade between 11 am and 3 pm when it's sunny. Step out of the sun before your skin has a chance to redden or burn.*
- *When choosing a sunscreen look for a high protection SPF (SPF 30 or more) to protect against UVB, and the UVA circle logo and/or 4 or 5 UVA stars to protect against UVA. Apply plenty of sunscreen 15 to 30 minutes before going out in the sun and reapply every two hours and*

straight after swimming and towel-drying.

- *Keep babies and young children out of direct sunlight.*
- *The British Association of Dermatologists recommends that you tell your doctor about any changes to a mole or patch of skin. If your GP is concerned about your skin, make sure you see a Consultant Dermatologist on the GMC specialist register – an expert in diagnosing skin cancer. Your doctor can refer you for free through the NHS.*
- *Sunscreens should not be used as an alternative to clothing and shade, rather, they offer additional protection. No sunscreen will provide 100% protection.*
- *It may be worth taking Vitamin D supplement tablets (available from health food stores) as strictly avoiding sunlight can reduce Vitamin D levels.*

Vitamin D advice

The evidence relating to the health effects of serum Vitamin D levels, sunlight exposure and Vitamin D intake remains inconclusive. Avoiding all sunlight exposure if you suffer from light sensitivity, or to reduce the risk of melanoma and other skin cancers, may be associated with Vitamin D deficiency. Individuals avoiding all sun exposure should consider having their serum Vitamin D measured. If levels are reduced or deficient, they may wish to consider taking supplementary vitamin D3, 10-25 micrograms per day, and increasing their intake of foods high in Vitamin D such as oily fish, eggs, meat, fortified margarines, and cereals. Vitamin D3 supplements are widely available from health food shops.

WHERE CAN I GET MORE INFORMATION?
